VEGFR2 Expression in Head and Neck Squamous Cell Carcinoma Cancer Cells Mediates Proliferation and Invasion

Hui-Min Xu¹*, Jian-Guo Zhu¹, Lian Gu¹, Song-Qun Hu², Hao Wu²

Abstract

Vascular endothelial growth factor 2 (VEGFR2) was initially identified as a receptor of VEGF on endothelial cells with a role in regulating angiogenesis during organism development and tumorigenesis. Previously, in cancer tissue, VEGFR2 has been reported to be expressed in endothelial cells. In our research, we found that VEGFR2 was expressed not only in endothelial cells but also cancer cells in head and neck squamous cell carcinomas (HNSCCs). Knockdown of VEGFR2 in Hep2 cells could arrest the cell cycle in G0/G1, leading to a decrease in proliferation. We also present evidence that MAPK/ERK signal pathways and expression of CDK1 downstream of VEGFR2 might regulate proliferation and cell cycle arrest. Furthermore, we discovered that down-regulate VEGFR2 in Hep2 cells could significantly affect the invasion ability. Taken together, our data suggest that VEGFR2 might regulate proliferation and invasion in HNSCC cancer cells in vivo.

Keywords: HNSCC - VEGFR2 - proliferation - invasion

Asian Pac J Cancer Prev, 17 (4), 2217-2221

Introduction

Head and neck squamous cell carcinoma (HNSCC), which is diagnosed 500,000 new cases every year, is ranked among the 10 most common cancers worldwide (Rothenberg and Ellisen, 2012; Das et al., 2014). Due to the large amount of people consuming cigarettes and severely air pollution in China, it is much higher risk to suffer from HNSCC in China (Pathare et al., 2011). Nowadays, the therapies of HNSCC are surgical resection combined with radiotherapy and chemotherapy. However, the deficiency of biomarker for diagnosis and prognosis causes the low survival rate of HNSCC patients who diagnosed at advanced stages (Reya and Clevers, 2005; Rehman and Wang, 2009).

Vascular endothelial growth factor 2 (VEGFR2), also named as Kinase insert domain receptor (KDR), is a kind of type III receptor tyrosine kinase. It was first reported as the receptor of vascular endothelial growth factor (Parast et al., 1998). The activation of VEGFR2 leads to the proliferation, survival and permeability of endothelial cells via Raf/Mek/Erk, PI3K/Akt, and PI3K/Akt/nitric oxide pathways. Therefore, VEGFR2 is the key factor to mediate the angiogenesis during the process of development and tumorigenesis. So far, many drugs targeting VEGF2 has been developed and some of them work effectively (Gasparini et al., 2005; Krajewksa et al., 2015). Recently, VEGFR2 has been reported to express in the tumor cells besides the endothelial cells and the expression levels are associated with prognosis (Brekken and Thorpe, 2001; Ye et al., 2004; Guo et al., 2010). There is no previous research detecting the expression of VEGFR2 in the tumor cells of HNSCC. In order to assess the relationship of VEGFR2 and the tumorigenesis of HNSCC, we preformed immunohistochemical study on HNSCC tumors derived from 109 patients who undergone primary tumor resection in Affiliated Hospital of Natong University. We also examined the role of VEGFR2 in the proliferation and migration of Hep2 cancer cells which is a kind of human laryngeal carcinoma cell line.

Materials and Methods

Patients and tissue samples

The specimens of 109 tumor tissues and 28 para-carcinoma tissues were obtained from patients who underwent the surgery without previous chemotherapy and radiotherapy at ENT head and neck surgery department, Affiliated Hospital of Nantong University from January, 2002 to May, 2010. The HNSCC specimens were formalin-fixed paraffin-embedded. The specimen arrays were provided by Shanghai Outdo Biotech Co., Ltd.

Reagents and antibodies

The following reagents and antibodies were used in this study: rabbit polyclonal anti- VEGFR2 (Abcam),

¹Department of Otolaryngology-Head and Neck Surgery, Changsha No.1 People's Hospital Affiliated to Soochow University, Changsha, ²Department of Otolaryngology-Head and Neck Surgery, Affiliated Hospital of Nantong University, Nantong, China

*For correspondence: 13921522245@163.com
mouse monoclonal anti-CDK1 (Abcam), rabbit polyclonal anti-ACTIN (Abcam), rabbit polyclonal anti-P-ERK (Abcam), goat polyclonal anti-HA (Abcam). Z-Leu-Leu-Leu-al (MG132) and Cycloheximide (CHX) were purchased from Sigma Aldrich.

**Western blot**

Tissue and cell proteins were immediately homogenized in a homogenization buffer containing 50 mM Tris-HCl, PH 7.5, 150 mM NaCl, 0.1% NP-40, 5 mM EDTA, 60 mM β-glycerophosphate, 0.1 mM sodium orthovanadate, 0.1 mM NaF and complete protease inhibitor cocktail (Roche Diagnostics), and then centrifuged at 12,000 g for 20 min to collect the supernatant. Protein concentrations were measured with a Bio-Rad protein assay (BioRad, Hercules, CA, USA). The supernatant diluted in 2×SDS loading buffer and boiled for 15 min. Proteins were separated with SDS-polyacrylamide gel electrophoresis (SDS-PAGE) and then transferred to polyvinylidenedifluoride filter (PVDF) membranes (Millipore, Bedford, MA). The membranes were blocked with 5% fat-free milk in TBST (150 mM NaCl, 20 mM Tris, 0.05% Tween-20) for 2 h at room temperature. Thereafter the membranes were washed with TBST three times and incubated overnight with the primary antibodies and then horseradish peroxidase-linked IgG as the secondary antibodies for 2 h at room temperature. The band density was determined by a computer-assisted image-analysis system (Adobe Systems, San Jose, CA) and normalized against ACTIN levels. Values were responsible for at least three independent reactions.

**Immunohistochemistry (IHC)**

Immunostaining was performed by using the avidin biotin peroxidase complex. The sections were deparaffinized with a graded ethanol series, and endogenous peroxidase activity was blocked by soaking in 3% hydrogen peroxide for 30 min. Then, the sections were processed in 10 mmol/L citrate buffer (PH = 6.0) and heated to 121°C in an autoclave for 20 min to retrieve the antigen. After rinsing in PBS (PH = 7.2), the sections were then incubated with anti-VEGFR2 antibody (diluted 1:200) for 2 h at room temperature. Negative control slides were processed in parallel using a nonspecific antibodies and horseradish peroxidase-linked IgG as the secondary antibodies for 2 h at room temperature. The band density was determined by a computer-assisted image-analysis system (Adobe Systems, San Jose, CA) and normalized against ACTIN levels. Values were responsible for at least three independent reactions.

**MTT (Dimethyl thiazolyldiphenyltetrazolium) Assays**

At 24, 48 and 72 hours after transfection, the cells were harvested for MTT assay. Hep2 cells were seeded at 5.0 × 10^3 cells per well in the 96-well plates with five replicate wells for each condition. Every 24 h after transfection, 20μl MTT (Sigma, St. Louis, MO) reagent was added to respective wells, and the incubation continued for 4 h. After the incubation, the supernatant was removed and 100μl dimethylsulfoxide (DMSO) was added to dissolve the formazan crystals. Optical density (OD) value of each sample was measured at a wavelength of 570 nm on an enzymed-linked immunosorbent assay plate reader (Bio-Rad, Hercules, CA). All experiments repeated three times.

**Cell cycle analyses**

Migration of Hep2 cells was assayed using chamber with 8 Impore filters (6.5 mm film diameter, 8 Impore size, Corning, USA). At 48 hours post-transfection, cells were plated at a density of 5.0 × 10^4 per insert in the upper chamber without serum. Medium with 20% FBS was added to the lower chamber as chemo-attractant. After incubation for 24 h, non-invading cells were removed from the top with a cotton swab, cells that migrated to the bottom of the membrane were then fixed with 95% ethanol and stained with 0.2% crystal violet for 30 min at 37°C and washed twice with PBS. Then stained cells were visualized under a microscope (high-power fields), counted in five random fields, and the average number was taken.

**Results**

**VEGFR2 express in the tumor cells of HNSCC**

Expression level of VEGFR2 in the HNSCC was examined for 109 tumor tissues and correspond para-carcinoma tissues via immunehistochemical staining. In the para-carcinoma group, VEGFR2 expressed only moderately in the endothelial cells (Figure 1A, B). On
the contrary, VEGFR2 expression was observed to be strongly and stably localized in both endothelial cells and surrounding tumor cells. (Figure 1 C, D)

**VEGFR2 siRNA can inhibit the proliferation of Hep2 cells**

To validate the function of VEGFR2 in tumor cells, we used Hep2 cells as *in vitro* modal. First, western blot was used to test the expression of VEGFR2 in Hep2 cells and the efficiency of siRNA which targeting VEGFR2. Compared with control and negative siRNA group, the expression of VEGFR2 was significantly down regulated (*p*<0.05). (Figure 2 A, B) Then, we applied MTT colorimetry to examine the proliferation ability of Hep2 cells transfected by VEGFR2 siRNA. At both 24h and 48h after transfection of siRNA, the absorption values for VEGFR2 siRNA group were significantly lower than the blank control group (*p*<0.01), while there were no effects in the negative siRNA group. (Figure 2 C)

Since VEGFR2 siRNA affects proliferation, we performed flow cytometric analysis to access the cell cycle progression at 48 hours after VEGFR2 siRNA transfection of Hep2 cells. As showed in Figure 3, the percent of cells in G0/G1 phrase was 61.04% in VEGFR2 siRNA group compared with 31.05% in control group. Consistently, the ratio of cells in S and G2/M phrases drops to 24.50% and 14.46% respectively. While in siRNA group, the ratio is 40.23% and 28.72% in control group.

**p**-ERK and CDK1 act as the downstream of VEGFR2 to regulate the Hep2 proliferation. Western blot shows that the VEGFR2 siRNA significantly decreases the level of *p*-ERK (A, B) (*p*<0.05) and the expression of CDK1 (C, D) (*p*<0.05)

Figure 1. VEGFR2 Expresses in HNSCC Tumor Tissue and Para-carcinoma Tissues. (A, B) VEGFR2 expresses in HNSCC para-carcinoma tissues. (C, D) VEGFR2 expresses in HNSCC tumor tissue. Arrows indicate the expression cells

Figure 2. Knockdown of VEGFR2 can affect the Hep2 cells proliferation. (A,B) Western blot analysis shows that siRNA targeting VEGFR2 can decrease the expression of VEGFR2 (*p*<0.05). (C) MTT assay shows that both at 24h and 48h after transfection of siRNA, the proliferation ability of Hep2 cells is reduced (*p*<0.01)

Figure 3. VEGFR2 siRNA Arrest the Cell Cycle at G0/G1. (A) The distribution of phases of Hep2 cells treated by control siRNA (B) The distribution of phases of Hep2 cells treated by VEGFR2 siRNA

Figure 4. The Invasion Ability of Hep2 is Significantly Reduced by VEGFR2 siRNA. The Hep2 cells treated with control siRNA (B) and VEGFR2 siRNA (A) or without siRNA (C) are planted into transwell chambers to measure the immigration ability (**p*<0.01)
ERK and CDK1 regulate the proliferation downstream of VEGFR2

To further clarify the mechanism of VEGFR2 knocking down induced anti-proliferation, we examined the expression and phosphorylation level of relating gene-CDK1 and p-ERK. The result of western blot demonstrated that the phosphorylation level of ERK (Figure 4 A,B) and the expression of CDK1 (Figure 4 C,D) decreased significantly (P<0.05).

Down-regulation of VEGFR2 leads to decrease invasion ability of Hep2 cells

Transwell assay was used to investigate the invasion ability of VEGFR2 down regulated Hep2 cells. The results showed that VEGFR2 siRNA significantly reduced the invasion of Hep2 cells compared with blank control group. While the negative control siRNA remained the same as blank group. (p<0.01)(Figure 5)

Discussion

The tumorigenesis is a complex procedure, involving multiple genes and environmental factors, among which angiogenesis plays an important role in this process. If the diameter exceeds the minimal size (1-2mm), the solid tumors require a vascular stroma (Folkman and Shing, 1992). VEGFR2 was firstly identified as the receptor of vascular endothelial growth factor (VEGF) and proved to mediate the process of angiogenesis in the endothelial cells (Segiet et al., 2015). Therefore, the previous researches of VEGFR2 focused on its function of angiogenesis. However, our research revealed that VEGFR2 expressed strongly not only in the endothelial cells but also in tumor cells in HNSCC, which consisted with reports in other cancer (Guo et al., 2010; Silva et al., 2011; Mokhtari, 2012; Kontic et al., 2014). This result indicated that VEGFR2 might play an important role in progression of HNSCC.

There were few researches focusing on the VEGFR2’s functions in cancer cells before, therefore our study was designed to recognize the effect of VEGFR2 down-regulation. We used Hep2 cell line as cell model. Previously, researchers have proved that the proliferation ability wasone of key factors for tumorigenesis (Cheng et al., 2008; Kauppila et al., 2014). According to our study, MTT assay shown that the down-regulation of VEGFR2 via siRNA can significantly decrease the proliferation in Hep2 cells. In order to make clear the reason why proliferation was inhibited, we performed flow cytometric analysis. The result showed that more cells were arrested in the G0/G1phases compared with control group. As a result, we tested the expression of CDK1 which was the key regulator of G1/S checkpoint (Corlu and Loyer, 2012), at protein level. The expression of CDK1 was significantly suppressed which may explain the cell cycle arrest. MAPK/ERK was reported to act as the downstream of VEGFR2 to transport the proliferation signal (Schulze et al., 2005), so the phosphorylation level of ERK was determined by western blot. P-ERK level reduced significantly which demonstrated that MAPK/ERK signal pathway might be activated by VEGFR2 to mediate CDK1 expression and affect the cell cycle. It has been reported that invasion is essential in HNSCC development (Inglehart et al., 2014). Therefore, we examined invasion ability of Hep2 cells by transwell assay. VEGFR2 knockdown significantly affected Hep2 cell invasion.

Previous researches have certified that VEGF was observed in cancer cells (Bergers and Benjamin, 2003). Autonomous VEGF synergized with EGFR signaling is essential for squamous carcinoma cell proliferation independent of angiogenesis. In this work, they identified VEGFR1 and Neuropilin-1 as the receptor for VEGF (Lichtenberger et al., 2010). Though still in debate, cancer stem cell was thought to be the causes of recurrence and metastasis. VEGF-Neuropilin 1 loop was reported to be important in cancer stemness (Beck et al., 2011). Both of them did not detect the expression of VEGFR2 in skin cancer cells. On the contrary, we observed the expression of VEGFR2 in cancer cells in HNSCC. It is possible that VEGFR2 also involves in the regulation of proliferation and invasion in the HNSCC in vivo.

VEGFR2 has been realized as the target for anti-cancer therapy for its function on angiogenesis (Croci and Rabinovich, 2014; Xuan et al., 2014). Our research illustrated that VEGFR2 could also mediate the proliferation and invasion in Hep2 cells which caste a light on developing anti-tumor therapy targeting on VEGFR2 not only its function on angiogenesis but also anti-proliferation and anti-invasion in HNSCC.
