# Probabilities of Developing Cancer over the Life Span of a Japanese - Update 

Manami Inoue ${ }^{1}$, Suketami Tominaga ${ }^{2}$

#### Abstract

In a previous study, we investigated the probability of developing cancer in the entire life span of a Japanese using population-based cancer incidence data from 1994, to obtain a relevant index of the impact of cancer occurrence on the Japanese population (APJCP, 1: 333-336, 2000). In the present paper, we have updated the information using the latest reports on cancer incidence in Japan in 1998. A method based on the cumulative risk of cancer was employed to estimate the probability of developing cancer up to 84 years of age, the average life expectancy of a Japanese female, and 79 years of age, the average life expectancy of a Japanese male. The time trend was also analyzed from 1975-1998. The cumulative risk of developing cancer in any site up to 84 and 79 years of age was $45 \%$ and $\mathbf{3 6 \%}$ for males, $\mathbf{2 7 \%}$ and $\mathbf{2 1 \%}$ for females, and $\mathbf{3 5 \%}$ and $\mathbf{2 8 \%}$ for both genders, respectively. The cumulative risk showed an increasing time trend before leveling-off after 1985. From our results, it is expected that nearly onethird of Japanese males and one-fourth of Japanese females will develop cancer by the time they reach the average life expectancy.

Key Words: lifetime probability - cumulative risk - Japan
Asian Pacific J Cancer Prev, 4, 199-202

## Introduction

For estimating the probability of developing cancer over the entire life span (lifetime risk) as a relevant index of the impact of cancer occurrence, a method based on cumulative risk was introduced and presented in our previous report (Inoue et al, 2000). The estimates of cancer incidence in Japan for 1994 (The Research Group for Population-based Cancer Registration in Japan, 1999) were used, the most recent data available at the time of the study. The data are now available for up to 1998 (The Research Group for Population-based Cancer Registration in Japan, 2003). In view of the importance and growing need of this kind of information for policy makers and public health workers as well as cancer researchers, we updated the estimation for the Japanese population based on the latest data available and expanded the estimation to male- and female aggregates.

## Methods

The present study used the data cancer incidence in Japan for 1998 , the most recent data available from the research
group for Population-based Cancer Registration in Japan (The Research Group for Population-based Cancer Registration in Japan, 2003). The computerized data file with the data from 1975 to 1998 was obtained from the research group via websites (http://www.mc.pref.osaka.jp/ocr/ registry/index.html) with permission. Incidence data were available for all major sites of cancer; oral cavity and pharynx, esophagus, stomach, colon, rectum, liver, gallbladder and biliary tract, pancreas, larynx, lung, skin, bladder, kidney, brain and central nervous system, thyroid, lymphoma, multiple myeloma, and leukemia for both genders, prostate for males, and breast, uterus and ovary for females. These sites are classified by the International Classification of Diseases, 10th revision (ICD-10) (WHO, 1992).

Based on the incidence data, a probability estimation was carried out by a method based on the cumulative risk of cancer. The cumulative risk of all sites and major sites of cancer was estimated from the cumulative incidence rates. Cumulative risk is the probability that an individual will develop the disease in question during a certain age period in the absence of any competing cause of death (Plummer,

*Average life expectancy of Japanese females, **Average life expectancy of Japanese males
1997). Cumulative incidence rates are sums of age-specific rates over a certain age range. They can be interpreted either as a directly age-standardized rate with the same population size in each age group, or as an approximation to the cumulative risk (Jensen et al, 1991; Day, 1992). This concept can be applied to the estimation of the probability of developing cancer over one's entire life span. Thus, cumulative risks of all and major sites of cancer were calculated using the following formulae provided that age-
specific rates were given by 5 -year age-groups:
Cumulative rate of cancer (\%) $=$ $100 \times 5 \times \Sigma$ age -specific rate $\times 10^{-5}$

Cumulative risk of cancer (lifetime risk) $(\%)=$ $100 \times\{1-\operatorname{cxp}($-cumulative rate/100) $\}$

ICD-10th, International statistical classification of diseases and related health problems, 10th revision
*Average life expectancy of Japanese female, **Average life expectancy of Japanese male

## Detailed discussion of these statistics is found elsewhere (Day, 1992).

Age-specific incidence rates of all sites and major sites of cancer were derived from the above-mentioned estimates

Figure 1. Time Trend in the Average Life Expectancy among Japanese in 1975-2000
in Japan for 1998. For the period of life span used in the present study, we referred to the average life expectancy at birth in Japan (Ministry of Health and Welfare, 2000) and tried to calculate the cumulative rates and corresponding cumulative risks from age 0 to 79 (nearly corresponding to the average life expectancy for males in 1998) and 84 (correspond to the average life expectancy for females in 1998) for males, females, and both genders.

Additionally, we calculated the cumulative risk of cancer at all sites for the age ranges 0-74, 0-79 and 0-84 in 1975, $1980,1985,1990,1995$, in addition to 1998 , to access the time trend of lifetime risk of developing cancer.

## Results and Comments

Estimated lifetime probabilities of developing all sites and major sites of cancer are shown in Table 1. The cumulative risk of developing cancer at any site up to 84 and 79 years of age was $45 \%$ and $36 \%$ for males, $27 \%$ and $21 \%$ for females, and $35 \%$ and $28 \%$ for both genders, respectively. The results for major sites of cancer are also shown in this table.

For reference, the time trend in the average life expectancy at birth in Japan by the Ministry of Health and Welfare (Ministry of Health and Welfare, 2000) was shown in figure 1 . An apparently increasing trend was observed for both genders during 1975-1998, from 72 to 77 in males, and from 77 to 84 in females. Accordingly, the time trend in the lifetime probability of developing cancer was presented

Figure 2. Time Trend in the Lifetime Risk (cumulative risk) (\%) of Developing Cancer from 0 to 74, 79 and 84 years of Age among Japanese in 1975-1998
in figure 2, by cumulative risk for age from 0 up to 74,79 and 84 , which approximate the average life expectancy in these periods. The cumulative risk showed an increasing time trend before leveling-off after 1985. The increasing trend was more marked in males than in females. In females, no remarkable increment in the cumulative risk was observed after 1985.

From these results, it is expected that nearly $36 \%$ of Japanese males and $27 \%$ of Japanese females will develop cancer by the time they reach the average life expectancy.
